NILPOTENCY DEGREE OF COHOMOLOGY RINGS
IN CHARACTERISTIC TWO

GEORGE S. AVRUNIN AND JON F. CARLSON

(Communicated by Maurice Auslander)

ABSTRACT. In this paper, we consider the cohomology ring of a finite 2-group with coefficients in a field of characteristic two. We show that, for any positive integer \( n \), there exists a 2-group whose cohomology ring has elements of nilpotency degree \( n + 1 \) and all smaller degrees.

1. INTRODUCTION

It is well known that the cohomology rings of finite groups with coefficients in fields of positive characteristic can contain nilpotent elements. But these cohomology rings are difficult to determine, so we do not know the detailed structure of very many examples. In particular, nothing appears to be known about the possible nilpotency degrees of elements in these rings. In this paper, we construct a family of finite groups \( G_n \) such that, for any field \( K \) of characteristic two, the cohomology ring \( H^*(G_n, K) \) contains elements of nilpotency degree \( j \) for all \( j \leq n + 1 \). Unfortunately, our methods do not generalize to the case of odd characteristic. Indeed, if \( K \) is a field of odd characteristic \( p \), we know of no examples of elements of \( H^*(G, K) \) having nilpotency degree greater than \( p \).

2. THE GROUP \( G_n \)

Fix an integer \( n > 1 \) and a field \( K \) of characteristic two. We describe a group \( G = G_n \) in terms of an abelian normal subgroup \( N \), the quotient \( Q \), and the 2-cohomology class corresponding to the central extension \( N \rightarrow G \rightarrow Q \).

Let \( N = \langle a_1, \ldots, a_n \rangle \) and \( Q = \langle z_1, \ldots, z_n \rangle \) be elementary abelian 2-groups of rank \( n \). Then the cohomology rings \( H^*(N, K) \) and \( H^*(Q, K) \) are polynomial rings in \( n \) indeterminates over \( K \). We write \( H^*(N, K) = K[a_1, \ldots, a_n] \) and \( H^*(Q, K) = K[\zeta_1, \ldots, \zeta_n] \), where \( a_i \) is the element of \( \text{Hom}(N, K) = H^1(N, K) \) dual to \( a_i \) and \( \zeta_j \) is the element of \( \text{Hom}(Q, K) \) dual to \( z_j \).

Let \( E^*_{*,*} \) be the Lyndon-Hochschild-Serre spectral sequence for the cohomology of the extension with coefficients in \( K \). Since \( N \) is central in \( G \),
Q acts trivially on $H^*(N, K)$ and $E_2^{r,s} = H^r(Q, H^s(N, K)) \cong H^r(Q, K) \otimes_K H^s(N, K)$. If $\chi \in Z^2(Q, N)$ is a cocycle representing the class of the extension $N \rightarrow G \twoheadrightarrow Q$, then the differential $d_2^{0,1}: H^1(N, K) \rightarrow H^2(Q, H^0(N, K)) = H^2(Q, K)$ is given by $d_2^{0,1}(\mu) = [\mu \circ \chi]$. Specifying appropriate values for the $d_2^{0,1}(\alpha_i)$ thus determines the class of $\chi$ and so the structure of $G$.

For $i = 1, \ldots, n$, define an element $\tau_i \in H^2(Q, K)$ by

$$\tau_i = \begin{cases} \zeta_1^2 & \text{for } i = 1, \\ \zeta_{i-1} \zeta_i + \zeta_i^2 & \text{for } i = 2, \ldots, n. \end{cases}$$

Now define $d_2^{0,1}$ by $d_2^{0,1}(\alpha_i) = \tau_i$.

A corresponding $\chi$ describing the extension $N \rightarrow G \twoheadrightarrow Q$ is then given by

$$\chi(\sum e_i z_i, \sum e'_i z_i) = e_1' e_1 a_1 + (e_1 e_2' + e_2 e_2') a_2 + \cdots + (e_{n-1} e_n' + e_n e_n') a_n,$$

where the $e_i, e_i' \in F_2$. The group $G$ is thus a group of order $2^{2n}$ generated by elements $u_1, \ldots, u_n$ subject to the relations $u_i^4 = 1$, $[u_i, u_{i-1}] = u_i^2$, and $[u_i, u_j] = 1$ if $j \neq i - 1, i + 1$.

3. THE SPECTRAL SEQUENCE

Let $R = K[x_1, \ldots, x_n]$ be a polynomial ring in $n$ indeterminates over $K$. Using the somewhat nonstandard, but convenient, notation of [2], we define the Koszul complex of $R$ as follows.

**Definition 3.1.** For each $i = 0, \ldots, n$, let $\mathcal{K}_i(R)$ be the free $R$-module with basis consisting of the symbols $b(S)$ indexed by the set of all subsets $S \subseteq \{1, \ldots, n\}$ with $|S| = i$. Define $\delta_i: \mathcal{K}_i(R) \rightarrow \mathcal{K}_{i+1}(R)$ by

$$\delta_i(f \cdot b(S)) = \sum_{j \in S} x_j f \cdot b(S \cup \{j\}), \text{ for all } f \in R.$$ 

Then $\delta_{i+1} \delta_i = 0$ and

$$\mathcal{K}(R): 0 \rightarrow \mathcal{K}_0(R) \xrightarrow{\delta_0} \mathcal{K}_1(R) \xrightarrow{\delta_1} \cdots \xrightarrow{\delta_{n-1}} \mathcal{K}_n(R) \rightarrow 0$$

is the Koszul complex of $R$.

Except for the indexing, $\mathcal{K}(R)$ is the standard projective resolution of $K$ as $R$-module [3], and we know its cohomology.

**Lemma 3.1.** The cohomology $H^*(\mathcal{K}(R))$ is $H^n(\mathcal{K}(R)) = K$.

**Definition 3.2.** Let $A$ be a finitely generated $R$-module. The Koszul complex of $A$, $\mathcal{K}(A)$, is defined to be $\mathcal{K}(A) = A \otimes_R \mathcal{K}(R)$.

Now make $H^*(Q, K) = K[\zeta_1, \ldots, \zeta_n]$ into an $R$-module by setting $x_i \cdot f(\zeta_1, \ldots, \zeta_n) = \tau_i f(\zeta_1, \ldots, \zeta_n)$. By [6, Proposition 3.1], $H^*(Q, K)$ is a free $R$-module. It follows that $H^i(\mathcal{K}(H^*(Q, K)))$ is zero unless $i = n$, and we see that $H^n(\mathcal{K}(H^*(Q, K)))$ is isomorphic to $H^*(Q, K)/I$, where $I$ is the ideal generated by the $\tau_i$, as in the previous section.
Consider an element \( \mu = f(\zeta_1, \ldots, \zeta_n) \otimes \alpha_1^{e_1} \cdots \alpha_n^{e_n} \) in \( E_2^{p, e_1+\cdots+e_n} \). Since \( d_2 \) is a derivation, \( d_2(\alpha_1^{e_1}) \) is zero when \( e_1 \) is even. Thus,
\[
d_2(\mu) = \sum f(\zeta_1, \ldots, \zeta_n) \tau_i \otimes \alpha_1^{e_1} \cdots \alpha_i^{e_i-1} \cdots \alpha_n^{e_n},
\]
where the sum is taken over those \( i \) such that \( e_i \) is odd. If the \( e_i \) are all even, we see that the complex
\[
0 \to H^*(Q, K) \otimes \alpha_1^{e_1+1} \cdots \alpha_n^{e_n+1} \xrightarrow{d_2} \sum_i H^*(Q, K) \otimes \alpha_1^{e_1} \cdots \alpha_i^{e_i} \cdots \alpha_n^{e_n} \xrightarrow{d_2} H^*(Q, K) \otimes \alpha_1^{e_1} \cdots \alpha_n^{e_n} \to 0
\]
is isomorphic to the Koszul complex \( \mathcal{A}(H^*(Q, K)) \). Since \( E_2 \) is a direct sum of such complexes and the cohomology of each complex is \( H^*(Q, K)/I \) in degree \( n \), we have proved

**Theorem 3.2.** \( E_3^{*, *}_n \simeq H^*(Q, K)/I \otimes K[\alpha_1^2, \ldots, \alpha_n^2] \).

**Corollary 3.3.** \( E_3^{*, *}_n \simeq E_3^{*, *}_n \).

**Proof.** We have seen that each \( \alpha_1^2 \) survives to \( E_3 \), and we note that \( \alpha_1^2 = \beta(\alpha_1) \), where \( \beta \) is the Bockstein operator. Since the transgression commutes with the Steenrod operations \([4, \text{II.9.c}]\), we have \( d_3(\alpha_1^2) = \beta(\tau_i) \), which is zero in \( E_3 \). It follows that each \( \alpha_i^2 \) survives to infinity, and then that all the higher differentials in the spectral sequence are zero. \( \Box \)

4. **The quotient** \( H^*(Q, K)/(\tau_1, \ldots, \tau_n) \)

We now exhibit elements of the ring \( E_3^{*, 0} = E_2^{*, 0}/d_2(E_2^{*, 1}) \) having nilpotency degrees \( 2, \ldots, n + 1 \). Since \( E_3^{*, 0} = E_\infty^{*, 0} \) is a subring of \( H^*(G, K) \), we will therefore produce elements of the same nilpotency degrees in the cohomology ring \( H^*(G, K) \).

Let \( I \) be the ideal generated by the elements \( \tau_1, \ldots, \tau_n \). Then \( I \) is the image of \( d_2 \) in \( E_2^{*, 0} \). We use Gröbner bases to show that, modulo \( I \), the element \( \zeta_i \) is nilpotent of degree \( i + 1 \).

We recall some basic definitions and results. Let \( k \) be a field and let \( k[x_1, \ldots, x_m] \) be the polynomial ring in \( m \) indeterminates over \( k \). Fix any order of the monomials \( x_1^{i_1} \cdots x_m^{i_m} \) such that

1. If \( a < b \) then \( ac < bc \) for any monomials \( a, b, \) and \( c \), and
2. \( a < ab \) for all monomials \( a \) and \( b \neq 0 \).

We can write any \( f \in k[x_1, \ldots, x_m] \) as a \( k \)-linear combination of monomials. The nonzero term \( a_{(i_1, \ldots, i_m)} x_1^{i_1} \cdots x_m^{i_m} \) such that \( x_1^{i_1} \cdots x_m^{i_m} \) is as large as possible with respect to the order \( \prec \) is called the principal term of \( f \). The monomial \( x_1^{i_1} \cdots x_m^{i_m} \) is called the principal monomial of \( f \). Now let \( B \) be a finite set of polynomials. A polynomial \( f \) is said to be reduced with respect to \( B \) if the principal monomial of \( f \) is not divisible by the principal monomial of any element of \( B \). By subtracting multiples of elements of \( B \) from \( f \), we can obtain a reduced polynomial that is congruent to \( f \) modulo the ideal generated by the elements of \( B \); such a polynomial is
a reduction of $f$ with respect to $B$. A set of generators $B$ for an ideal $I$ is called a Grobner basis for $I$ if, for every polynomial $f \in I$, every reduction of $f$ with respect to $B$ is zero. (In such a case, we say $f$ reduces to zero with respect to $B$.) We will need the following theorems [1].

**Theorem 4.1.** Let $f$ and $g$ be any two nonzero polynomials, and let $f_p$ and $g_p$ be their principal terms. The $S$-polynomial of $f$ and $g$, $S(f, g)$, is

$$S(f, g) = \frac{h}{f_p} f - \frac{h}{g_p} g,$$

where $h$ is the least common multiple of $f_p$ and $g_p$. A set of generators $B$ is a Grobner basis if and only if $S(f, g)$ reduces to zero with respect to $B$ for every $f, g \in B$.

**Theorem 4.2.** Let $B$ be a Grobner basis for an ideal $I$, and let $f \in k[x_1, \ldots, x_m]$. Then $f \in I$ if and only if $f$ reduces to zero with respect to $B$.

Now consider $H^*(Q, K) = K[\zeta_1, \ldots, \zeta_n]$. We order the monomials lexicographically with $\zeta_n > \zeta_{n-1} > \cdots > \zeta_1$. Then, for each $i = 1, \ldots, n$, the principal term of $\tau_i$ is $\zeta_i^2$.

**Proposition 4.3.** The set \{\tau_1, \ldots, \tau_n\} is a Grobner basis for the ideal $I = (\tau_1, \ldots, \tau_n)$.

**Proof.** We have $S(\tau_i, \tau_j) = \zeta_j^2 \tau_i + \zeta_i^2 \tau_j$, which reduces to zero. \(\square\)

**Proposition 4.4.** For $j = 1, \ldots, n$, $\zeta_j \notin I$ and $\zeta_j^{j+1} \in I$.

**Proof.** The element $\zeta_1 \cdots \zeta_j$ is congruent to $\zeta_j^j$ modulo $(\tau_1, \ldots, \tau_n)$, so it suffices to show that $\zeta_1 \cdots \zeta_j$ does not belong to $I$. But $\zeta_1 \cdots \zeta_j$ is reduced with respect to the Grobner basis \{\tau_1, \ldots, \tau_n\}.

Clearly, $\zeta_1^2 = \tau_1 \in I$. For $j > 1$, we have

$$\zeta_j^{j+1} = \zeta_j^j \zeta_j + \left( \sum_{k=0}^{j-1} \zeta_j^{j-k} \zeta_j^k \right) \tau_j,$$

so $\zeta_j^{j+1}$ does belong to $I$. \(\square\)

Thus, the image of $\zeta_j$ in $E_3^{1,0} = E_\infty^{1,0}$ has nilpotency degree $j + 1$.

We sketch another argument. The quotient $K[\zeta_1, \ldots, \zeta_n]/I$ is a finite-dimensional algebra, so the set \{\tau_1, \ldots, \tau_n\} is a system of parameters and the corresponding variety is a complete intersection. Then $K[\zeta_1, \ldots, \zeta_n]/I$ has dimension exactly $2^n$. This is a consequence of Bézout's Theorem. Unfortunately, we know of no really good reference. The reader is referred to [5] for a general treatment or to [7, Appendix 6] for something more specific.

From this, it is easy to see that the set consisting of the monomials $\zeta_1^{i_1} \cdots \zeta_n^{i_n}$ for which each $i_k$ is either zero or one is a basis for $K[\zeta_1, \ldots, \zeta_n]/I$, and this implies that the element $\zeta_1 \cdots \zeta_j$ is not in $I$ for $j = 1, \ldots, n$. Since $\zeta_j^j$ is congruent to $\zeta_1 \cdots \zeta_j$ modulo $I$, $\zeta_j^j$ does not belong to $I$.
